Equipment Data:

The six fields under Equipment Data are specified on the Overpressure Scenario Form.

Input Data:

The form fields for inputs are blue and organized under the Scenario Input column. The are described below:

Length – Vessel seam-to-seam length for horizontal and vertical orientations. Not required for spheres.

LengthUnits – Units (ft, in or mm) associated with the Length.

Diameter – Vessel diameter generally taken as the outer diameter.

DiameterUnits - Units (ft, in or mm) associated with the Diameter.

Orientation - Vessel orientation (horizontal, vertical or spherical.

Head1Type - Both vessel heads assumed the same (2:1 ellipsoidal, hemispherical or flat).

UserArea – Any wetted area beyond normal geometry calculation to be added such as a boot or piping.

Level – Vessel liquid level for use in determining wetted area.

LevelBasis – Source for input liquid level such as LSHH, LSH, Upper LG Tap.

Height - Elevation above grade of vessel bottom for use only when considering maximum fire height

Adequate Drainage - If yes then 21,000 used in heat equation, if no 34,500 used in heat equation

Insulation F – Insulation factor used to reduce total heat input. 1.0 unless fireproof insulation is present then either 0.3 or calculated per API STD 521.

Include Entire Area – If yes then entire surface area is used for heat input calculation regardless of level (conservative).

Pop – Operating pressure used to quantify initial density and initial relief temperature. Higher value results in higher density and lower initial relief temperature.

Pop Basis – Source of operating pressure such as PSHH, PSH, Operating.

Bubblepoint Liquid – If yes, vapor composition and properties will be quantified based on liquid with PQFlash. If no, vapor stream with components in same order and Top are required to be entered.

Top – Only required if Bubblepoint is false, otherwise calculated. Higher value results in lower density and higher initial relief temperature.

SetP – Set pressure that will be used along with overpressure to determine relief pressure.

OverP – Allowable overpressure typically 21% used to determine relief pressure.

P3 – Constant back pressure when PSV is closed.

DeltaT – Temperature increment to be used for each expansion step used for required relief rate calculation.

ThermoPackage – Thermo package used for properties. VMG (Symmetry) packages or REFPROP 10.0 from NIST

LiquidStreamID – The liquid or supercritical stream initially contained in the vessel. A new stream can be added here. If initially supercritical, level should be 100% and VapStreamID = LiqStreamID. See <u>Stream</u> <u>Definition Form</u>.

VapStreamID – The vapor or supercritical stream initially contained in the vessel. A new stream can be added here. If initially supercritical, level should be 100% and VapStreamID = LiqStreamID. See <u>Stream Definition</u> Form.

Kdv – Manufacturer's certified vapor Kd or 0.975 for API STD 520 default.

Kdl – Manufacturer's certified liquid Kd or 0.65 for API STD 520 default.

Sizing – PSV sizing method: API 520 Vapor or Numerical Integration (recommended when Z <= 0.8).

OutPipeSizing – Outlet pressure drop method: Adiabatic, Omega Method or Numerical Integration.

Calculation Method:

The calculation method for external fire with supercritical expansion is performed in two steps. The first step involves determining the overall heat input and initial relief conditions. The heat input is based on the vaporizing liquid equation that is well established in API STD 521. As indicated above, the heat input may be evaluated based on the starting liquid level assuming the fluid is subcritical at the entered operating conditions or may be evaluated on the total surface area regardless of the liquid level. The wetted area is then calculated based on the input dimensions, level (if applicable) and orientation of the vessel using standard geometric equations. The heat input is subsequently calculated based on the wetted area using the following equations depending on the presence of adequate drainage and firefighting equipment:

Adequate drainage and firefighting equipment:

 $HeatInput = 21,000 \times InsulationF \times WettedArea^{0.82}$

No adequate drainage and firefighting equipment:

 $HeatInput = 34,500 \times InsulationF \times WettedArea^{0.82}$

The initial relief conditions are based on the input operating conditions and stream compositions. If the fluid is identified as a bubblepoint liquid at operating conditions, the liquid stream is set at the bubblepoint and the temperature and vapor stream composition are calculated using the selected thermodynamic package. If the fluid is not identified as a bubblepoint liquid, then it is required to enter the temperature and vapor stream composition. Note that in this case the components for the liquid and vapor stream need to be entered in identical order. The starting liquid and vapor densities are quantified using the selected thermodynamic package and the liquid and vapor volumes are quantified using the input liquid level and standard geometric equations which yields the overall starting vessel mass and density. The composition of the overall supercritical relief stream is then determined by mathematical addition of the liquid and vapor moles for each component divided by the total moles present.

The second calculation step involves successive expansions of the fluid based on the input DeltaT. The StartT, which is the intial temperature at the relief pressure prior to any fluid leaving the equipment, is first calculated by performing a PD Flash using the InitialDensity and P2 (relief pressure). A PT Flash is then performed to StartT + DeltaT to determine a new density and fluid properties. The rate of fluid loss during this expansion is quantified as follows:

AvgMass = (DensityStart + DensityStop)/2 * TotalVol

AvgCp = (Cp Start + CpStop)/2

IncHeat = AvgMass * AvgCp * DeltaT

TimeInc = HeatInc / HeatInput

RequiredRate = (DensityStart - Density End) * TotalVol / TimeInc

VolRate = RequiredRate / ((DensityStart + Density Stop)/2)

The process is repeated for successive increases in temperature by DeltaT to determine the maximum VolRate which represents the maximum required area for the scenario. Note that this is not necessarily the maximum mass flow rate.

Scenario Output Data:

The form fields for scenario-specific outputs are organized under the Scenario Output column. These are described below:

WettedArea – Surface area calculated using level plus UserArea or total surface area plus UserArea.

HeatInput – Calculated total heat input based on WettedArea, F and Adequate Drainage selection.

Vrhoop – Vapor density at input operating conditions

Lrhoop - Liquid density at input operating conditions

TotalVol – Total volume based on input dimensions

InitialMass - Total of vapor and liquid mass quantified based on relative volumes and densities

LiqMass - Total liquid mass based on level and liquid density

VaporMass - Total vapor mass based on level and vapor density

InitialDensity – Overall bulk density prior to any relief/loss of fluid

InitialSpecVol – 1 / InitialDensity

InitialRelTemp – Predicted temperature at which the relief pressure will be achieved and relief initiated

StartT - Starting temperature for maximum volumetric expansion rate which is basis for required rate

CriticalPres - Overall fluid critical pressure

CriticalTemp - Overall fluid critical temperature

AvgMass - Average mass over maximum volumetric expansion temperature increment

DensityStart - Density at Start T of maximum volumetric expansion temperature increment

CpStart – Mass heat capacity at Start T of maximum volumetric expansion temperature increment

CpStop - Mass heat capacity at StopT (T2) of maximum volumetric expansion temperature increment

AvgCp – Average Cp over maximum volumetric expansion temperature increment

HStart - Mass enthalpy at Start T of maximum volumetric expansion temperature increment

HStop - Mass enthalpy at StopT (T2) of maximum volumetric expansion temperature increment

MaxVolume – Maximum volumetric flowrate found from all expansions

IncHeat – Total heat added during StartT to StopT (T2)

IncTime – Time to heat from StartT to StopT (T2)

Flux2 – RequiredRateMass · RequiredArea * 144 / 3600

Kd - Discharge coefficient used to evaluate required area

Scenario Calculation Results:

The form fields for overall scenario results are organized in the Scenario Calculation Results Section. These outputs are typical of most of the scenario calculations and are detailed under Typical Scenario Calculation Results.

QA/QC Benchmarks:

As the calculation of the wetted area relies on simple geometric calculations and the heat input calculation is very straightforward as detailed in the calculation section, the primary benchmark for the external fire with supercritical expansion is the quantification of the initial relief composition and associated overall density followed by calculation of the expansion rate over each temperature increment. These two calculations were benchmarked against a commercial simulation (Symmetry) for a typical Cold Separator NGL liquid in a separator. The initial relief composition, density (18.1 lb/ft³) and temperature (~ 35° F) were found to be nearly identical between Pressio and the simulator. The maximum expansion rate from Pressio was then recreated in the simulator from 215.5° F to 225.5° F to determine the required relief rate of 17,472 lb/hr versus 17,484 lb/hr from Pressio. Finally, the entire calculation was benchmarked against an internal RKR spreadsheet which determined an overall required relief rate of 17,415 lb/hr with similar intermediate results.

External Fire Supercritical Fluid Expansion

V-2000 External Fire

Equipment Data:

Equipment Tag:	V-2000	Туре:	Pressure Vessel
Drawing:	PID-2000	MAWP:	1000 psig
Description:	Low Temperature Separator	MAWT:	-100 F

Scenario Description:

The Low Temperature Separator contains liquid hydrocarbon that could vaporize in the event of an external fire potentially resulting in overpressure. However, the fluid will be supercritical at the relief pressure of 1,210 psig, therefore the required relief rate was based on the expansion rate of the fluid with the normal liquid composition and associated dewpoint vapor at normal operating conditions of 700 psig and -20 F.
